

Recently our 1 year old female 10 lb. spayed cat went in for her annual vaccinations. She was given an injection in the left and right hind quarters and one between the shoulders. She was also given pink drops in the nose. On the way home she started to vomit and defecate in the car. At home she began to pant very heavily and her eyes became glassy. We ran her back to the vet and they put her on oxygen and anti-histamines (sp?). Her breathing improved but she started vomiting with blood and diarrhea with blood. We were aloud to take her home and were told to watch her. She seemed to stabilize somewhat but was very weak and disoriented. We gave her water by syringe in the mouth to help avoid dehydration. A day later she died. The vet feels she had a reaction to the Feline Leukemia injection. Is this common? Is there anything else we could have tried? We felt so bad because she was so young and healthy before the injections. She did not have any problems with her first vaccinations a year ago after we adopted her. Thank you for any assistance.
